Abstract. Portal Catalogs is a popular means of searching for information on the Web. They provide querying and browsing capabilities on data organized in a hierarchy, on a category/subcategory basis. This paper presents mining techniques on user navigational patterns in the hierarchies of portal catalogs. Specifically, we study and implement navigation retrieval methods and clustering tasks based on navigational patterns. The above mining tasks are quite useful for portal administrators, since they can be used to observe users' behavior, extract personal preferences and re-organize the structure of the portal to satisfy better user needs and navigational habits. These mining tasks have been implemented in the NaviMoz, a prototype system for mining navigational patterns in portal catalogs.

1 Introduction

Portal catalogs provide querying and browsing capabilities on data organized in a hierarchy on a category/subcategory basis. Users can navigate these hierarchies to identify data of their preference. Examples of such catalogs can be found in all popular search engines, e.g. in Google, Yahoo, OpenDirectory Project. Also, portal catalogs of a specific subject or domain (e.g. e-marketplaces for hardware, portals for cultural information) are provided by user communities on the Web. Such catalogs, known as vertical portals, is a valuable collection of resources for anyone who needs to search for information relevant to the interests of those communities. Portal catalogs maintain large volumes of information resources which is not possible for a single user to classify and exploit. For this reason, they are quite popular as a means for searching information on the Web.

A key point for maintaining portal catalogs is to observe users' behavior and extract personal preferences in order to re-organize the structure of the portal to satisfy better user needs. To support such tasks, current approaches [8, 10, 1] examine the pages that users visit by investigating the web logs of proxy servers. However, observing visited pages, without also paying attention to the categories in which these pages have been classified, cannot give an indication of the user *navigational habits*.

Navigational habits are related with how users search and browse in the paths of a hierarchy in a portal catalog. Paths in hierarchies provide a conceptual clustering of Web pages in groups sharing common properties. During a Web page search and browsing in a portal catalog, users may visit categories, go forward in subcategories if they look for pages with specific content or go backwards in more general categories if they look for Web pages with general content. We call *navigational patterns* the paths that users follow in the hierarchy of a portal catalog during a Web page search and browsing. Observing *navigational patterns* can give an indication of the concepts that users are interested in, and their navigational habits, and better support the maintenance of the portal catalog. For example, knowing that the navigational pattern `/gadgets/sound/mp3-players` is quite popular among users, the portal administrator may decide to put a link for the category `mp3-players` in the first level of the portal hierarchy to provide users with instant access to the list of mp3 players available. Also, discovering that many users go back and forth several times within a navigational pattern, might be an indication that the specific part of portal hierarchy is not well-designed and users cannot easily determine which category to follow. In this case, the administrator may decide to change that part, providing new categories or eliminating some of the old ones.

This paper develops mining techniques on user navigational patterns in the hierarchies of portal catalogs. Specifically, the work studies and implements navigation retrieval capabilities and clustering tasks based on common navigational patterns. The above mining tasks are quite useful for portal administrators for customizing the structure of portal catalog according to user and navigational habits. We next summarize the contributions of our work:

1. We introduce navigational patterns for hierarchies of portal catalogs.
2. We suggest a metric to capture the structure and content similarity between two navigational patterns.
3. We study and implement mining tasks for user navigational patterns in the hierarchies of portal catalogs. We develop navigation retrieval methods, and clustering tasks based on navigational patterns. In navigation retrieval methods, given navigational patterns as input, we determine users that follow navigational patterns which have common characteristics compared to those input patterns. In clustering tasks, we determine user groups that share common navigational habits.
4. The above tasks are implemented in the NaviMoz, a prototype system for mining navigational patterns in portal catalogs.

1.1 Related Work

Bioinformatics is one of the research fields where mining patterns (similar to navigational patterns that we study here) is a popular research issue. Biological entities, such as proteins and molecules, consist of sequences of elements, in the same way that the navigational patterns consist of sequences of categories of the portal hierarchy [7, 9, 5]. However, in this field, user requirements are different

and, thus, mining tasks needed are different, too (e.g. one can ask for the co-factors of a reaction) [7].

Also, there are many approaches that exploit Web logs of proxy servers to observe users behavior in Internet sites [4, 8, 10, 11, 17]. They are based on the words related to the hyper-links that users click and on the keywords related to the target Web pages. Some of those approaches [2, 10] assist the creation of user communities, that is groups of users with similar interests. In [17], a new algorithm is presented, which supports sequence discovery from multidimensional data, allowing the detection of sequences across monitored attributes, such as URLs and http referees. As noted in the introduction, observing visited pages, without also paying attention to the categories in which these pages have been classified, cannot give an indication of the user navigational habits, as studied in this paper. Thus, we believe that our work is complementary to the approaches that exploit Web logs. For a detailed discussion on web mining techniques for web personalization see [1].

The shape definition language (SLD) presented in [18] is also related to our work. The SDL language is used to retrieve objects based on shapes contained in the histories associated with these objects. The notion of shapes is close to the notion of navigational patterns.

The rest of the paper is organized as follows. Section 2 introduces navigational patterns in the hierarchies of portal catalog, and defines a similarity metric for navigational patterns. Section 3 presents the mining tasks developed. Section 4 describes our prototype system, and finally, Section 5 concludes the paper.

2 Hierarchies and Navigational Patterns in Portal Catalogs

Portal catalogs classify information resources in a semantically meaningful way. Their purpose is to develop and maintain specific communities of interests on the Web. Portal catalogs maintain large volumes of information resources, organized in thematic categories. The overall structure of a portal catalog is actually a hierarchy on a category/subcategory basis.

We can represent a hierarchy of a portal catalog as a graph structure $G = (V, E)$. V is the set of nodes representing categories included in the hierarchy, and E is the set of edges representing category/subcategory relationship. Since we represent a hierarchy of a portal catalog as a graph structure, a user can reach a category following different paths. For example, one reaches the category **History** through either **Science/Social Science/History** or through **Society/History**.

A user, during a Web page search and browsing in a portal catalog, may visit several categories. We call the sequence of categories in those visits **navigational patterns**. We note that such patterns may include multiple occurrences of categories. This might be the result of users going back and forth several times within a path in the graph of hierarchy.

A key issue for developing mining tasks for navigational patterns is to be able to estimate how similar two navigational patterns are. In the next subsection we present a similarity metric to estimate the similarity degree between two navigational patterns in terms of structure and content.

2.1 A Similarity Metric for Navigational Patterns

We design a similarity metric for navigational patterns in hierarchies of portal catalogs that takes into consideration both the structure of the pattern and the keywords used as labels for the categories.

1. To estimate the structure similarity between two navigational patterns, we consider the elements of navigational patterns as character sequences and we exploit the metric suggested in [12]. Such a metric is based on the minimum cost sequence of *edit operations* needed to change one string to become identical to another string. The set of edit operations include deletion of a character, insertion of a character and replacement of a character with another one. The calculation of the metric is based on a dynamic programming algorithm. The final result is the sum of the costs of the considered operations divided by the sum of the lengths of the navigational patterns. The result expresses a distance d . Thus, in order to have the similarity we should calculate $1 - d$.
2. To estimate the content similarity between two navigational patterns, we calculate the ratio of the number of occurrence of the common categories in both patterns to the total number of categories in both patterns.

The similarity metric is calculated as the average of structure and content similarity.

Let for example $A = /Health/Medicine/Fitness$ and $B = /Health/Fitness/Running/Training/Coaching/Training$ be two navigational patterns. Their structural distance is 0.55 (delete **Medicine** from A and insert **/Running/Training/Coaching/Training** : 5 operations, total length=9). Thus, their structural similarity is 0.45. The ratio of the number of occurrence of the common categories in both patterns to the total number of categories in both patterns is $4/9 = 0.44$. Thus, the similarity between these two navigational patterns is 0.445.

3 Mining Tasks

We study and implement mining tasks for user navigational patterns in the hierarchies of portal catalogs. Specifically, we develop navigation retrieval tasks and clustering tasks based on navigational patterns.

3.1 Navigation Retrieval Tasks

In all navigational retrieval tasks, a navigational pattern is given as input. Based on this input pattern, we can determine users that follow navigational patterns

with common characteristics compared to the input pattern. All tasks can be performed for a certain time period provided by the user. Specifically, we have developed the following navigation retrieval tasks:

- *Retrieval of navigations which are supersets of the input pattern.* This task identifies users whose navigational patterns contain all the categories from the input pattern (but these are not the only ones in the user pattern), keeping their ordering. For example, given that `/Arts/Radio` is an input pattern, the following navigational patterns will be part of the answer:
 - `/Arts/Radio/Personalities/Henrie_Phil/Personalities/Radio/Personalities/Programs/Voice_Actors`
 - `/Arts/Radio/Guides/Directories/Directories`
- *Retrieval of navigations which are subsets of the input pattern.* This task identifies users whose navigational patterns contain only categories from the input pattern (but these are not the only ones in the user pattern), keeping their ordering. For example, given that `/Arts/Radio/Guides` is an input pattern, the following navigational patterns will be part of the answer:
 - `/Arts/Radio`
 - `/Arts/Guides`
- *Retrieval of navigations which are identical to the input pattern.* This task identifies users whose navigational patterns contain all the categories from the input pattern (and these are the only ones in the user pattern), keeping their ordering.
- *Retrieval of the navigations which are similar to the input pattern.* This task identifies users whose navigational patterns are similar to the input pattern, given a similarity threshold. The threshold is provided by the user. A navigational pattern is retrieved as part of the answer if the similarity metric (introduced in the previous section) between itself and the input pattern gives a value that exceeds the threshold provided. We note that the suggested similarity metric takes into consideration both the structure of the pattern and the keywords used as labels for the categories. For example, given that `/Arts/Music` is an input pattern, and the threshold is 0.70, the pattern `/Arts/Radio/Music` will be retrieved (similarity=0.81), but the pattern `/Arts/Radio` will not (similarity=0.62).

3.2 Clustering Tasks

In clustering tasks, we can determine user groups that share common navigational habits. All tasks can be performed for a certain time period provided by the user. Specifically, we have developed the following tasks:

- *Grouping users that follow similar navigational patterns.* To support this task we have implemented two clustering algorithms: the K-means and the single link hierarchical clustering algorithm [13, 14]. For both clustering algorithms we exploit the similarity metric suggested in the previous section. For the K-means algorithm, the user should provide the number of clusters

expected. For the single link algorithm, the user can either provide a clustering level, or ask the system to estimate one. The estimation of clustering level is performed using the C-index method [16] implemented for the single link clustering in [15].

- *Retrieval of the most popular navigations.* This task identifies the navigational patterns which have been followed by the majority of users. We consider such patterns as popular patterns.
- *Retrieval of the most undecided users.* This task identifies users whose navigational habits indicate that they are undecided during their search and browse in the portal hierarchy. Also, it ranks the users according to how much undecided they are. We suppose that when a user goes back and forth during searching and browsing, he/she is an undecided user. An example of a navigational pattern which shows that the respective user is undecided is the following: /Arts/Music/Pop/Music/Pop/Concerts/Pop/Music/Rock/Concerts. A user whose navigational pattern is /Arts/Music/Rock/Music/Rock/Concerts is less undecided than the former, due to lower number of *back and forth* (*B&F*) movements.

To support the last task, we have implemented an algorithm which counts how many *B&F* movements a user has made. The term *B&F* refers to a pair of categories in the hierarchy of a portal catalog. A pair of categories (*A*, *B*) is *B&F* if:

- Both *A* and *B* belong to the same navigational pattern *P*.
- $label(A) = label(B)$: the categories are the same.
- There is an odd number of categories (different than *A* and *B*) between *A* and *B* in pattern *P*.
- $label(after(A)) = label(before(B))$ (*after*(*A*) gives the category which is after *A* in the examined navigational pattern, while *before*(*A*) gives the category which is before *A* in the examined navigational pattern).

According to the above, a *B&F* pair appears in the primitive navigational pattern *A/B/A*. We call such *B&F* pairs as *basic B&Fs*, since the patterns in which can appear are of minimum length. The algorithm first detects the basic *B&Fs*, and then the others.

Input: navigational pattern

Output: number of the *B&F* pairs in the pattern.

Algorithm:

array BF: For every category of the input pattern, it contains its *B&F* partner (i.e., the category with which it constitutes a *B&F*).

Vector P: Contains all category pairs (*A*, *B*) which are candidates for *B&Fs*, and the number of categories that exist between *A* and *B*.

Vectors valueVector: One vector for each category, having the place where the category occurs in the navigational pattern.

int counter: Contains the number of *B&F*.

/*Find basic B&F */

```

for all categories
  if the size of the current category valueVector >1
    Check whether there are two successive occurrences in
    places i and j of the category in the pattern, such that
    no other category exists between places i and j.
    If there are not such successive occurrences then
      if one category exists between places i and j.
        B&F exists for category in i and category in j
        Add B&F to array BF
      else
        if N categories exist between places i and j,
        with N odd
          candidate B&F exists for category in i and
          category in j
          add this category pair to Vector P

Sort Vector P according to the number of categories that exist
between categories which constitute a candidate B&F.

/*Find the rest B&F */

for every pair (A,B) of the sorted Vector P
  Check if the categories after(A) and before(B) form a pair in
  array BF, and if so, the pair (A,B) is B&F.
  Update array BF
  else
    Find the category in array BF that constitutes a B&F pair
    together with after(A)
    If that category is before(B)
      Add the B&F pair to array BF
    else
      Find the category in array BF that constitutes a B&F pair
      together with BF[after(A)]

/*Computation of the total number of B&F */

For every non-zero element of array BF, increase counter by 1.
Return counter.

```

An example is given in case the input to the algorithm is the navigational pattern: *r/s/m/d/m/o/m/s/f/s/f/w/f/w*. The algorithm first detects the basic *B&Fs*, which are the category pairs (2, 4)¹ (i.e., m and m), (4, 6), (11, 13), (7, 9), (8, 10) and (10, 12) (i.e., f and f), and updates the array BF. Vector P keeps the category pair (1, 7) as a candidate *B&F*. The algorithm examines the category pair (2, 6) and finds that there exist *B&F* pairs (1, 4) and (4, 6). Thus, the pair (1, 7) is *B&F*.

¹ numbers denote places in the navigational pattern

3.3 User Identification Tasks

These tasks provide useful information regarding user identification. Specifically, the system provides (a) user navigation retrieval for a given time period, and (b) user session retrieval for a given time period.

4 System Description

The above tasks are implemented in the NaviMoz, a prototype system for mining navigational patterns in portal catalogs. NaviMoz system consists of three basic modules:

1. User Manager Module. This module provides user login operations and maintains the user access to the portal catalog. The users' navigations are stored in the database and they are further explored by the system's manager.
2. Mining Module. This module provides all the mining tasks for navigational patterns described in this paper.
3. Storage Module. This module is responsible for maintaining an RDBMS used for storing users information and their navigational patterns.
4. Presentation Module. This module supports the graphical interface of NaviMoz.

The architecture of NaviMoz is presented in Figure 1, while a screen dump showing a clustering task running is illustrated in Figure 2. Clustering has identified a cluster involving three users (Christodoulou Eleni, Kalimerh Maria and Kanellakopoulos Haralampos) whose navigational habits are similar.

5 Conclusions

Observing user behavior and extracting personal preferences is crucial for maintaining portal catalogs. Certain navigational habits can indicate the need to re-organize the structure of the portal to satisfy better user needs. Observing visited pages in a portal catalog, without also paying attention to the categories in which these pages have been classified, cannot give an indication of the user navigational habits.

This paper suggests a set of mining tasks on user navigational patterns in the hierarchies of portal catalogs. Those mining tasks can help portal administrators for customizing the structure of portal catalog according to user and navigational habits. In our work, we introduced navigational patterns for hierarchies of portal catalogs, and we designed a metric to capture their structure and content similarity. Based on this metric, we implemented several mining tasks, like navigation retrieval methods and clustering methods, for user navigational patterns in the hierarchies of portal catalogs.

The navigational patterns can be considered as simplified Xpath queries [19]. We will extend our work to employ complex navigational patterns (e.g., branching path expressions), expressed as Xpath pattern queries. Our future plan for

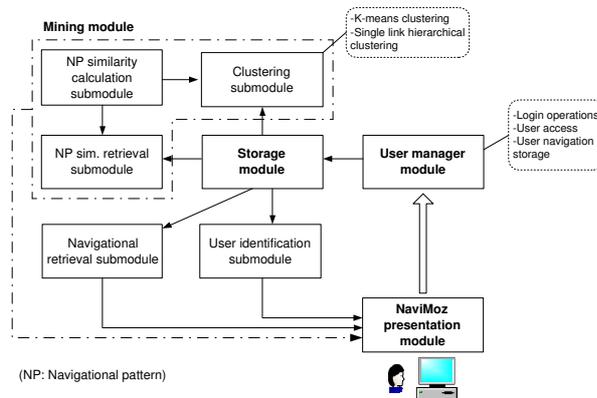

Fig. 1. Architecture of NaviMoz.

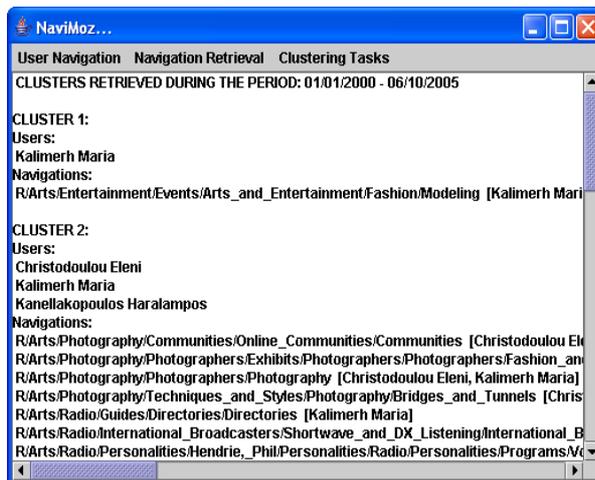

Fig. 2. Clustering task in NaviMoz.

NaviMoz is to become a full-fledged generic portal management system that will provide editing operations fully supported by the mining tasks described in this paper.
